Python › Formatting: Provider (Also modified in: Workspace)
 Provider for formatting. Possible options include 'autopep8', 'black', and 'yapf'.
 black

Shortcut to format python code in vscode. How to format python in vscode. How to format python code in visual studio. Format python code in vscode. Python vs c# code examples. How to put python in visual studio code. Auto format python code in vscode. Automatically format python code in vscode.

Black is "the uncompromising Python code formatter." It can be configured to automatically format your code whenever you save a file in VSCode. Install Black in your virtual environment: Install Microsoft's Python extension in VSCode: Open your VSCode settings, by going 'Code -> Preferences -> Settings'. Search for "python formatting provider" and select "black" from the dropdown menu. In the settings, search for "format on save" and enable the "Editor: Format on Save" option. Black will now format your code whenever you save a *.py file. Before saving: After saving: More: How to set Black line lengths in VSCode images from VSCode using Hyper Term Theme. Once suspended, adamolombard will not be able to comment or publish posts until their suspension is removed. Once unpublished, all posts by adamolombard will become hidden and only accessible to themselves. If adamolombard is not suspended, they can still re-publish their posts from their dashboard. Thanks for keeping DEV Community safe. Here is what you can do to flag adamolombard: Make all posts by adamolombard consistently posts content that violates DEV Community's code of conduct because it is harassing, offensive or spammy. Report other inappropriate conduct Unflagging adamolombard will restore default visibility to their posts. Code formatting is supported using either one of yapf or autopep8. The default code format provider is autopep8. Auto Formatting Formatting the source code as and when you save the contents of the file is supported. Enabling this requires configuring the setting "editor.formatOnSave": true as identified here. Paths All samples provided here are for windows. However Mac/Linux paths are also supported. AutoPep8 You can configure the format provider by changing a setting in the User or Workspace settings file as follows: "python.formatting.provider": "autopep8" Installing autopep8 pip install pep8 pip install Custom Path This is generally unnecessary. As the Extension will resolve the path to the formatter based on Python executable being used or configured in python.pythonPath of settings.json. If this cannot be found, then the formatter will be resolved based on the current environment Path settings. If this is not the case or you wish to use another version of autopep8, all you need to do is configure the path as follows either in the User or Workspace settings file: "python.formatting.autopep8Path": "c:/path/autopep8.exe" Yapf You can configure the format provider by changing a setting in the User or Workspace settings file as follows: "python.formatting.provider": "yapf" Custom Path This is generally unnecessary. As the Extension will resolve the path to the formatter based on Python executable being used or configured in python.pythonPath of settings.json. If this cannot be found, then the formatter will be resolved based on the current environment Path settings. If this is not the case or you wish to use another version of yapf, all you need to do is configure the path as follows either in the User or Workspace settings file: "python.formatting.yapfPath": "c:/yapfPath/yapf.exe" Custom arguments to Yapf Custom arguments can be passed into yapf by configuring the settings in the User or Workspace settings as follows: "python.formatting.yapfArgs": ["-style", "(based on style: chromium, indent_width: 20)"] Installing Yapf pip install yapf Visual Studio Code is a powerful editing tool for Python source code. The editor includes various features to help you be productive when writing code. For more information about editing in Visual Studio Code, see Basic Editing and Code Navigation. In this overview, we will describe the specific editing features provided by the Python extension, including steps on how to customize these features via user and workspace settings. Autocomplete and IntelliSense IntelliSense is a general term for code editing features that relate to code completion. Take a moment to look at the example below. When print is typed, notice how IntelliSense populates auto-completion options. The user is also given a list of options when they begin to type the variable named, greeting. Autocomplete and IntelliSense are provided for all files within the current working folder. They're also available for Python packages that are installed in standard locations. Customize IntelliSense behavior To customize the behavior of the analysis engine, see the Python extension code analysis settings and autocomplete settings. You can also customize the general behavior of autocomplete and IntelliSense, even to disable these VS Code features entirely. See Customizing IntelliSense. Tip: Check out the IntelliCode extension for VS Code (preview). IntelliCode provides a set of AI-assisted capabilities for IntelliSense in Python, such as inferring the most relevant auto-completions based on the current code context. For more information, see the IntelliCode for VS Code FAQ. Enable IntelliSense for custom package locations To enable IntelliSense for packages that are installed in other, non-standard locations, add those locations to the python.autoComplete.extraPaths collection in the settings file (the default collection is empty). For example, you might have installed Google App Engine installed in custom locations, specified in app.yaml if you use Flask. In this case, you'd specify those locations as follows: Windows: "python.autoComplete.extraPaths": ["C:/Program Files (x86)/Google/google_appengine", "C:/Program Files (x86)/Google/google_appengine/lib/flask-0.12"] mac OS/Linux: "python.autoComplete.extraPaths": ["~/local/lib/Google/google_appengine", "~/local/lib/Google/google_appengine/lib/flask-0.12"] For more on IntelliSense generally, see IntelliSense. Troubleshooting IntelliSense If autocomplete and IntelliSense aren't working for a custom module, check the following causes: Cause Solution The path to the python interpreter is incorrect Make sure you selected a valid interpreter path by running the Python: Select Interpreter command (see Environments). The custom module is located in a non-standard location (not installed using pip) Add the location to the python.autoComplete.extraPaths setting and restart VS Code. While editing, you can right-click different identifiers to take advantage of several convenient commands Go to Definition (F12) jumps from your code into the code that defines an object. This command is helpful when you're working with libraries. Peek Definition (⇧F12) (Windows Alt+F12, Linux Ctrl+Shift+F10), is similar, but displays the definition directly in the editor (making space to avoid obscuring any code). Press Escape to close the Peek window or use the x in the upper right corner. Go to Declaration jumps to the point at which the variable or object being declared in your code. Peek Declaration is similar, but displays the declaration directly in the editor. Again, use Escape or the x in the upper right corner to close the Peek window. Quick Fixes The add imports Quick Fix allows you to quickly complete import statements. First, begin by typing a package name within the editor. You will notice a Code Action is available to automatically complete the line of source code (as long as you have the module installed within the environment). Hover over the text (marked with a squiggle) and then select the Code Action light bulb when it appears. You can then select from a list of potential imports. Note: The functionality in the below examples is provided by the Pylance language server. The add imports Code Action also recognizes some of the popular abbreviations for the following common Python packages: numpy as np, tensorflow as tf, pandas as pd, matplotlib.pyplot as plt, matplotlib, as mpl, math as m, scipy as sp, and holoviews as hv. The import suggestions list is ordered with support packages (or modules) at the top. It will also include statements for more modules and/or members (classes, objects, etc.) from specified packages. Run Selection/Line in Terminal (REPL) The Python: Run Selection/Line in Python Terminal command (Shift+Enter) is a simple way to take whatever code is selected, or the code on the current line if there is no selection, and run it in the Python Terminal. An identical Run Selection/Line in Python Terminal command is also available on the context menu for a selection in the editor. VS Code automatically removes indents based on the first non-empty line of the selection, shifting all other lines left when needed. Source code that runs in the terminal/REPL is cumulative until the current instance of the terminal is closed. The command opens the Python Terminal if necessary; you can also open the interactive REPL environment directly using the Python: Start REPL command. (Initial startup might take a few moments especially if the first statement you run is an import.) On first use of the Python: Run Selection/Line in Python Terminal command, VS Code may send the text to the REPL before that environment is ready, in which case the selection or line isn't run. If you come across this behavior, try the command again when the REPL has finished loading. Formatting Formatting makes code easier to read by human beings. It applies specific rules and conventions for line spacing, indents, spacing around operators, and so on. You can view an example on the autopep8 page. Keep in mind, formatting doesn't affect the functionality of the code itself. Linting helps to prevent errors by analyzing code for common syntactical, stylistic, and functional errors and unconventional programming practices. Although there is a little overlap between formatting and linting, the two capabilities are complementary. The Python extension supports source code formatting using either autopep8 (the default), black, or yapf. General formatting settings Setting(python.formatting) Default value Description provider "autopep8" Specifies the formatter to use, either "autopep8", "yapf", or "black". Formatter-specific settings The following settings apply to the individual formatters. The Python extension looks for the formatter in the selected interpreter. To use a formatter in another location, specify that location in the appropriate custom path setting. "python.formatting.blackPath" Specifies the path to the black formatter. "python.formatting.yapfPath" Specifies the path to the yapf formatter. "python.formatting.blackArgs" ["-style", "(based on style: chromium, indent_width: 20)"] Pop up with warning message Black does not support the "Format Select" command. black does not support formatting sections of code, it can be prevented with the following settings: ["editor.formatOnSaveMode": "file"]. Refactoring The Python extension adds the following refactoring functionalities: Extract Variable, Extract Method, Rename Module, and Sort Imports. Extracts all similar occurrences of the selected text within the current scope, and replaces it with a new variable. You can invoke this command by selecting the line of code you wish to extract as a variable. Then select the light-bulb that is displayed next to it. Extracts all similar occurrences of the selected expression or block within the current scope, and replaces it with a method call. You can invoke this command by selecting the lines of code you wish to extract as a method. Then select the light-bulb that is displayed next to it. Rename Module After a Python file/module is renamed, Pylance can find all instances that may need to be updated and provide you with a preview of all the changes. To customize which references need to be updated, you can toggle the checkboxes at the line or from the file level in Refactor Preview. Once you've made your selections, you can select Apply Refactoring or Discard Refactoring. Sort Imports Sort Imports uses the isort package to consolidate specific imports from the same module into a single import statement and to organize import statements in alphabetical order. Invoked by: Right-click in editor and select Sort Imports (no selection is required) Command Palette (⇧⌘P) (Windows, Linux Ctrl+Shift+P), then Python Refactor: Sort Imports Assign a keyboard shortcut to the python.sortImports command Custom arguments to isort are specified in the python.sortImports.args setting, where each top-level element, as separated by spaces on the command line, is a separate item in the array: "python.sortImports.args": ["-rc", "-atomic"]. To use a custom isort script, use the python.sortImports.path setting to specify the path. Further configurations can be stored in an .isort.cfg file as documented in isort configuration. Note: For those migrating from isortv4 to isortv5, some CLI flags and config options have changed, refer to the project's isortv5 upgrade guide.
